Introduction

01

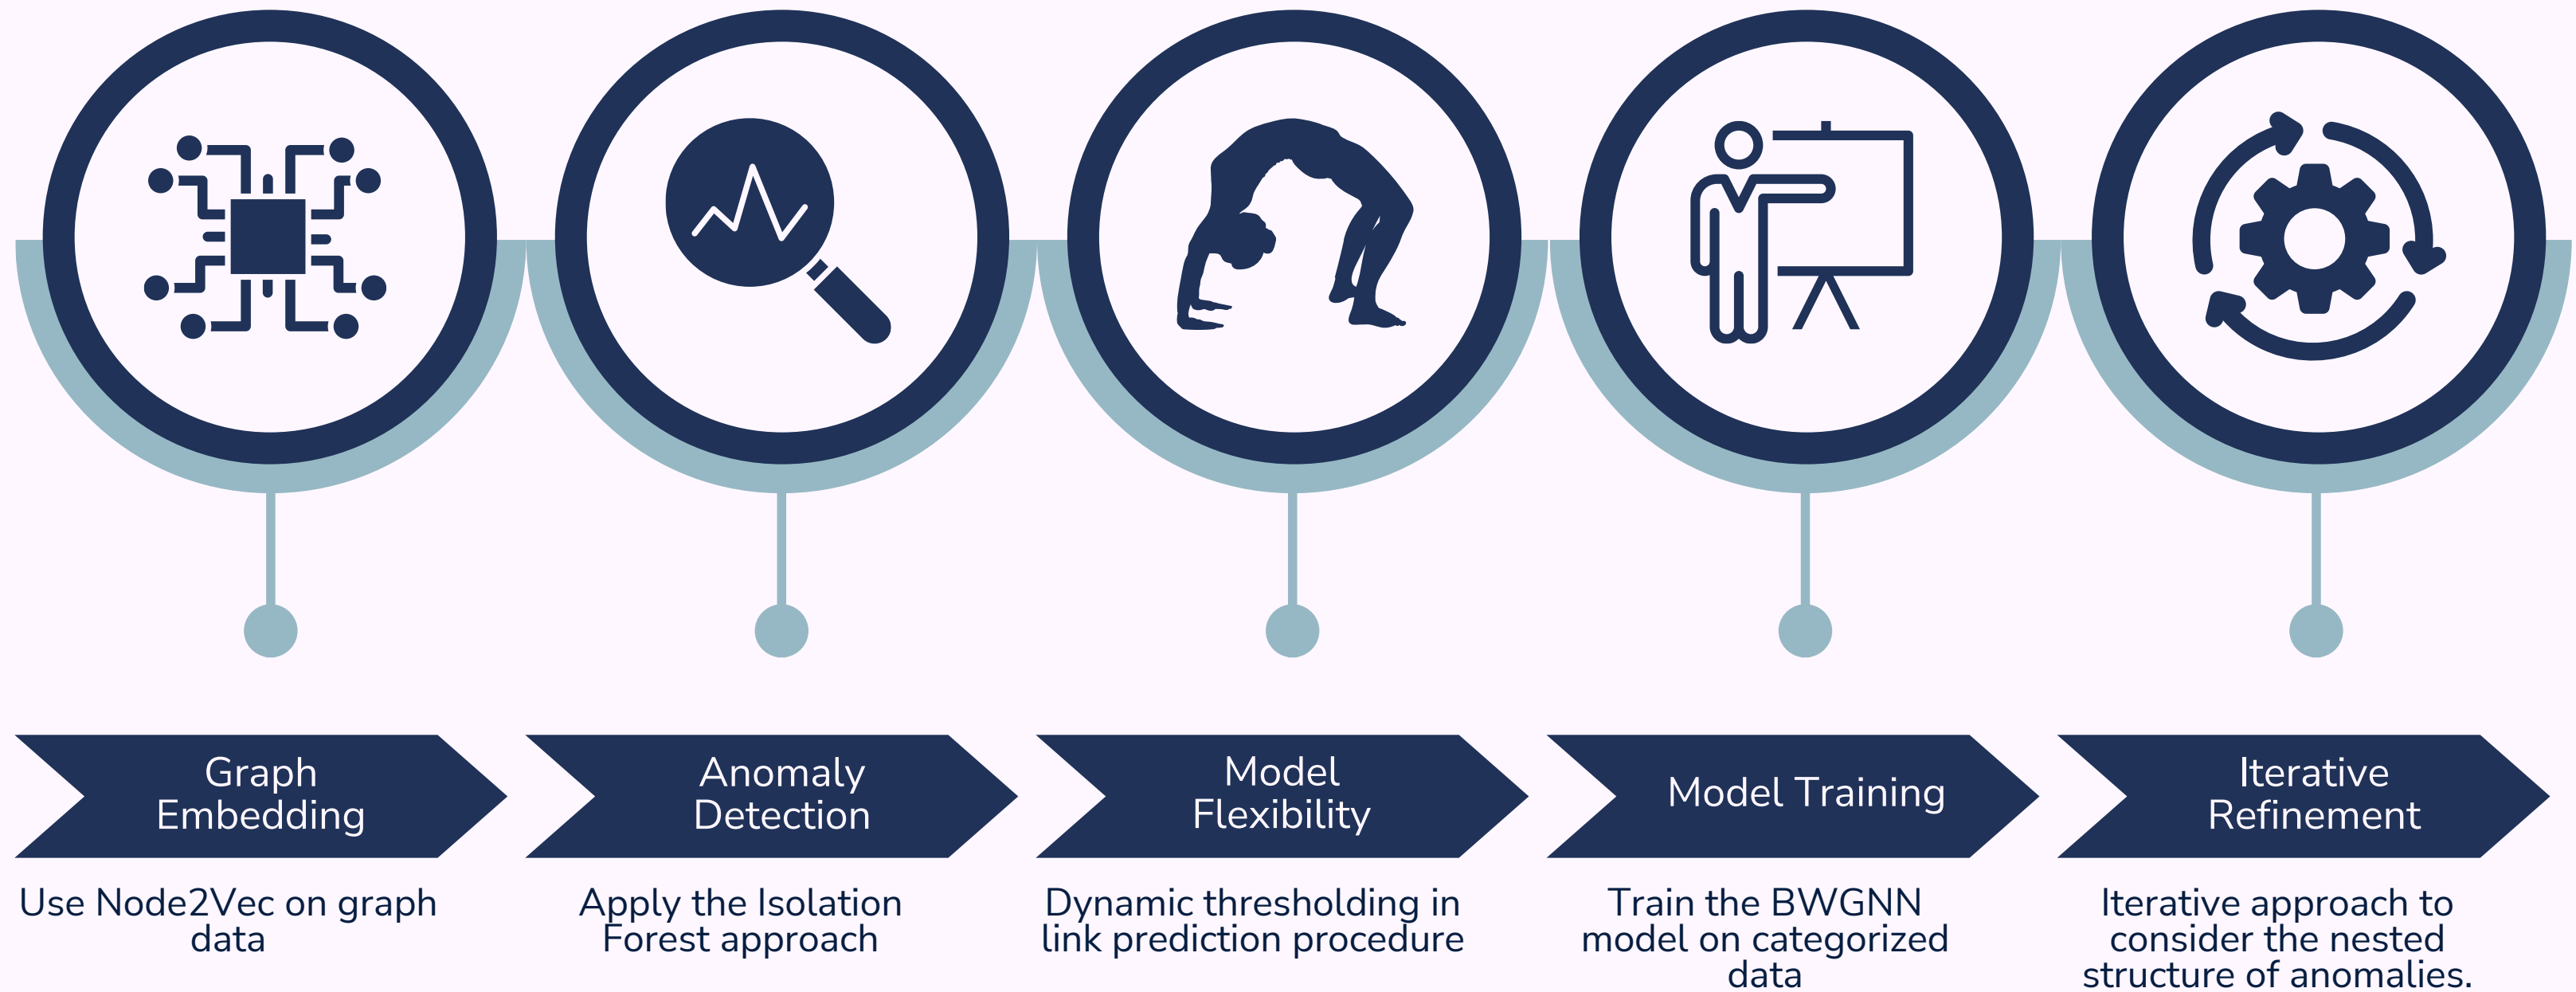

Leveraging BWGNNs combined
with Isolation Forest.

02

Detecting anomalies nodes in a nested
manner.

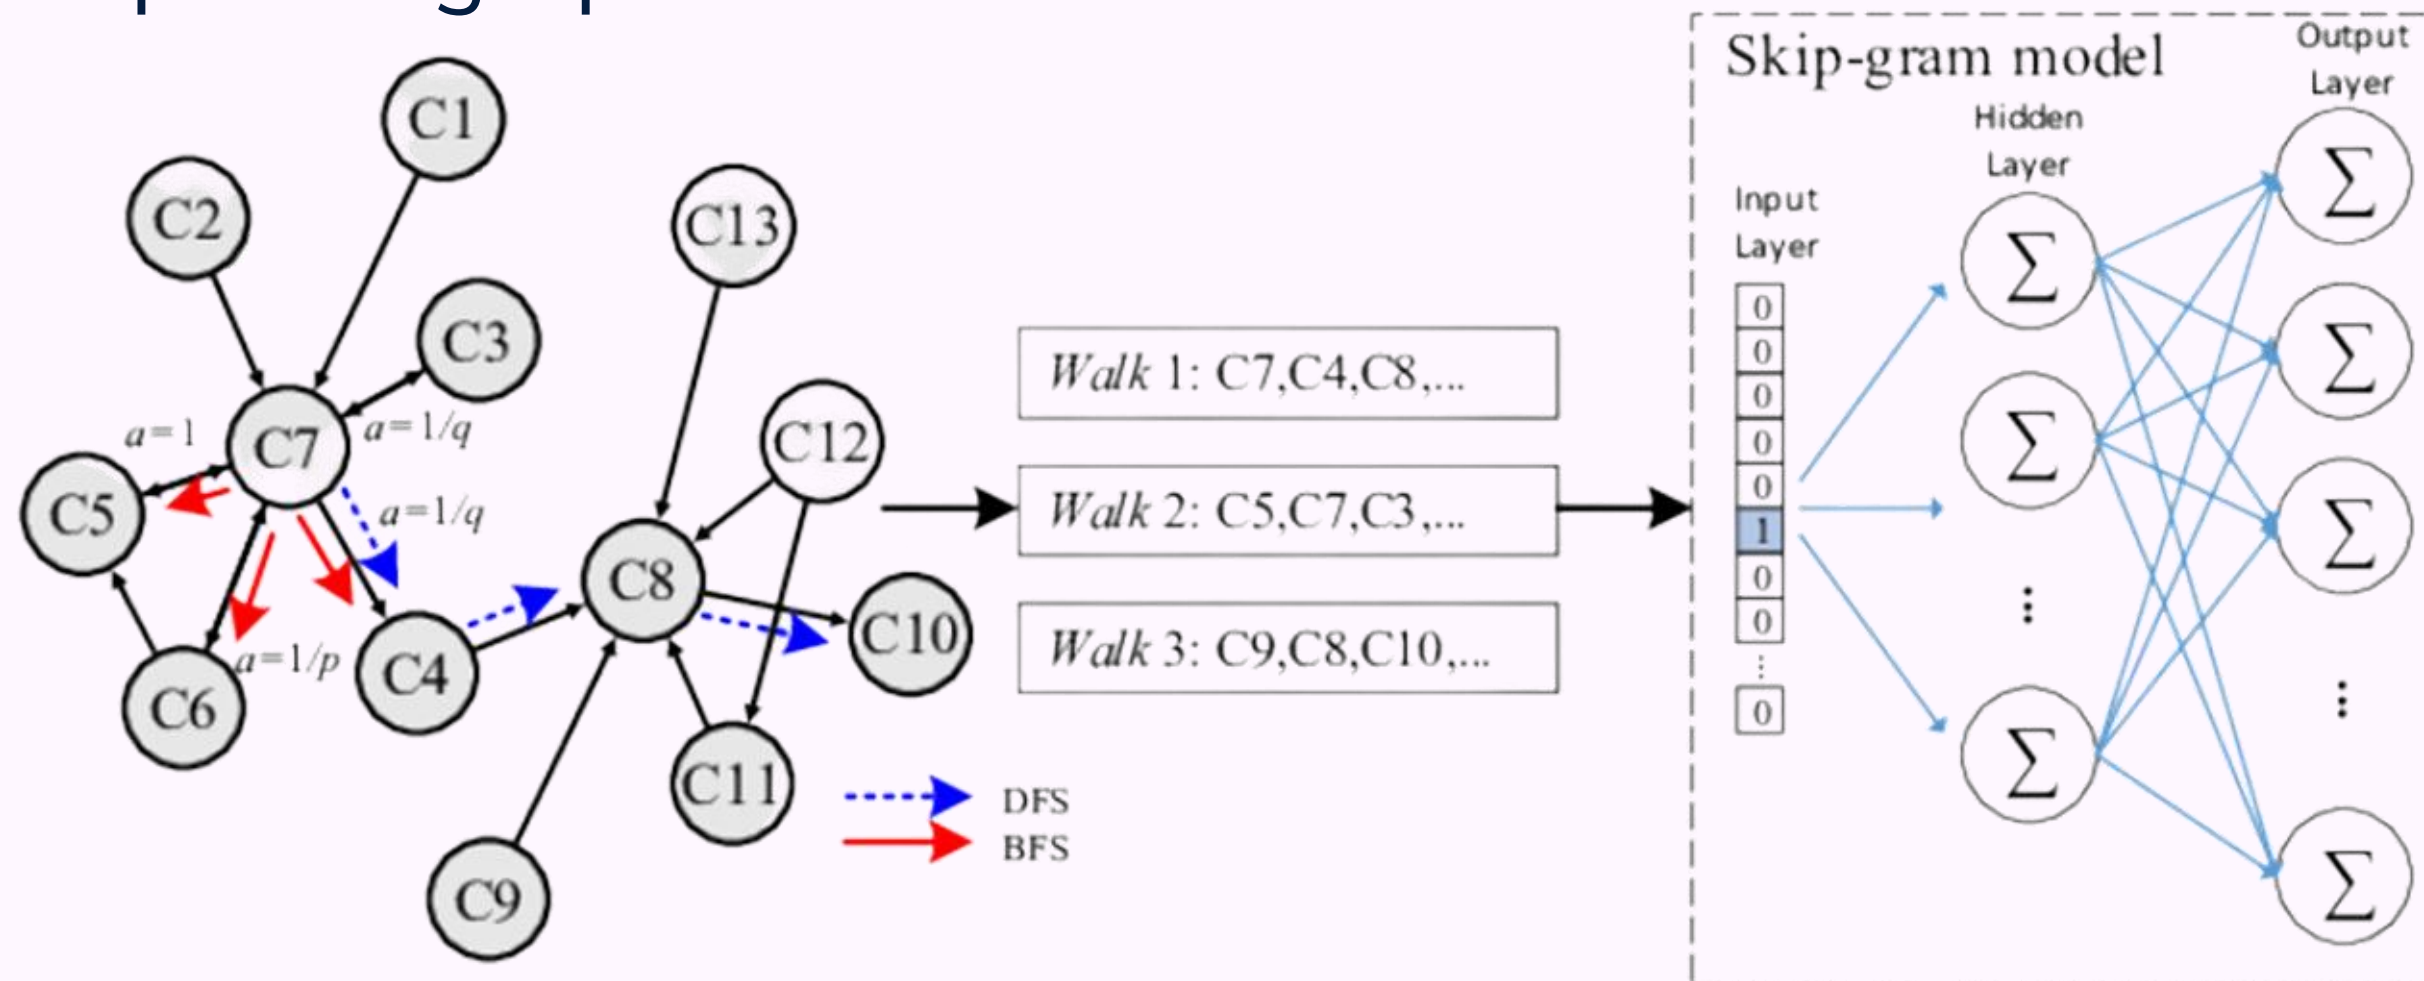

Requirements

1 Node embeddings

The Node2Vec approach is selected for graph embedding due to its flexibility in capturing the structural properties of nodes without over-relying on specific graph features.

The conceptual framework of node2vec.

2 Anomaly detection

Initially considered K-means clustering, but it is limited by data distribution assumptions and its struggle with high-dimensional data.

Aiming to train the network
anomaly set must be initialized.

Adopted the Isolation Forest
algorithm operating flexibility and
suitability on complex datasets.

3 Threshold

A threshold-based approach to classify nodes as anomalous using isolation scores is adopted, setting thresholds of 5%, 10%, and 20%.

Training is conducted using these two classes, updated during the iterations.

The nodes are categorized into kernel (normal) and residual (anomalous) sets.

4 Iterations

The iterative process of identifying and removing anomalies ensured a progressively adjusted graph, enabling more precise results in subsequent iterations.

This approach makes it possible to build a robust and adaptable anomaly detection system for graph-based datasets.

5

Apply the
BWGNN

BWGNN is an improved GNN, which employs Beta wavelets in parallel for each signal. These wavelets act as band-pass filters that since anomalous nodes distribute their spectral energy in high frequencies, capture anomalies effectively.

Final Solution

Node2Vec for
generating
embeddings

combining
BWGNN and
Isolation Forest
for effectiveness

Visualizations
and detailed
results

Final Solution

Six numerical experiments, including both BWGNN Hetero and Homo types, according to 5%, 10%, and 20% thresholding.

The results of each experiment are accurately documented.

Comparing the impact of different threshold settings and model variations on the system's performance.

Live Demonstration

The screenshot displays a Google Colab notebook titled "Phase_B.ipynb" in a web browser. The browser's address bar shows the URL: `colab.research.google.com/drive/1xqTA417LtVyykEBoeTnNHTMZHEZQteon#scrollTo=MQ1I2sEgKy5k&unic`. A green banner at the top of the browser window indicates "You are screen sharing" with a "Stop Share" button. The notebook interface includes a menu bar with options: File, Edit, View, Insert, Runtime, Tools, Help, and "All changes saved". On the left side, there are icons for file management and a search bar. The main code editor area contains the following Python code:

```
from google.colab import drive
import datetime
import os
drive.mount('/content/drive')

# Directory
directory = str(datetime.datetime.now()) + " BWGNN(hetero)" + " ISO with treshold = 5"

# Parent Directory path
parent_dir = '/content/drive/MyDrive/ColabNotebooks/Anom_Haar_pr/'

# Path
path = os.path.join(parent_dir, directory) + '/'
os.mkdir(path)
print(os.getcwd())
```

Below the code editor, a message states: "Drive already mounted at /content/drive; to attempt to forcibly remount, call drive.mount(\"/content/drive\", force_remount=True). /content".

The bottom section of the notebook shows the following imports:

```
[ ] import dgl
import torch
import torch.nn.functional as F
import argparse
import time
from datasets import Dataset
from sklearn.metrics import f1_score, accuracy_score, recall_score, roc_auc_score, precision_score, confusion_matrix
from sklearn.model_selection import train_test_split
import os
import sys
```

At the bottom of the screen, a Windows taskbar is visible with various application icons, a search bar, and a system clock showing 7:44 PM on 9/18/2024. A small notification at the bottom center of the Colab window says "Screen Recorder is sharing your screen." with "Stop sharing" and "Hide" buttons.

Outputs

	A	B	C	D	E	F	G
1	Node ID	Degree	Is Anomalous	Iteration 0	Iteration 1	Iteration 2	Iteration 3
2		0	3	0	0	0	0
3		1	3	0	0	0	0
4		2	5	0	0	0	0
5		3	1	0	0	0	0
6		4	5	0	0	0	0
7		5	3	0	0	0	0
8		6	4	0	0	0	0
9		7	1	0	0	0	0
10		8	3	0	0	0	0
11		9	2	0	0	0	0
12		10	2	0	0	0	0
13		11	2	0	0	0	0
14		12	4	0	0	0	0
15		13	2	0	0	0	0
16		14	5	0	0	0	0

Anomalies detected across all iterations.

 [Iteration 2 results.csv](#) 

 [Iteration 3 results.csv](#) 

 [Iteration 4 results.csv](#) 

Anomalous nodes identified in each cycle.

	A	B	C	D
1	Iteration 1	Iteration 2	Iteration 3	Iteration 4
2	518	386	343	265

Sum of anomalies in each iteration.

Distribution of isolation forest scores by nodes.

Threshold 5

Remain stable across all iterations.
This indicate a gentle approach to detecting anomalies.

Slightly decreasing across all iterations.
This indicate that nodes are being marked and removed from the middle areas.

Slightly increasing across all iterations.
This increase suggests that as the model processes more data and starts refining its detection.

Appears In this range only in the last iteration.
Which suggests that the model become more sensitive to certain types of behaviors that were not sufficiently pronounced in earlier iterations.

Threshold 10

Increases across iterations, indicating effective detection over time. However, there is a minor reduction in the final iteration, as some anomalies undergo reevaluation

Decreases over the iterations, which indicates that the model is becoming more precise in differentiating between normal and anomalous nodes.

Appears in the third iteration and increases, which suggests that the model is becoming more effective at distinguishing between what it considers normal behavior and anomalies.

Threshold 20

The count of nodes in this range is unstable because the model is dynamically adjusting its classification boundaries

Decrease that that anomaly is being detected and nodes from the mid-levels are filtered to the edges.

Increase in nodes that reflect the model's success in anomaly and normal detection.

The decrease at the end could reflect the model adjusting its sensitivity or re-evaluating nodes.

Large increase happened due to deeper insights gained from the data after multiple iterations.

Insights all histograms

5

Overly restrictive identification of anomalies, risking missing subtler anomalous patterns.

10

A balance between sensitivity and specificity.

20

Broader identification of anomalies, but with increased risk of misclassifying normal nodes as anomalous.

Lower thresholds are ideal for precision-focused tasks, while higher thresholds are better for environments where missing an anomaly could be detrimental.

Nested Iterations

Number of Anomalies vs Iteration

Prediction for Future Iterations

The predicted trend shows that future iterations will continue to detect fewer anomalies and converge.

Closer to Kernel Nodes

As iterations progress, the process of detecting and removing anomalies allows the model to get closer to identifying the kernel nodes which considered as normal.

Nested Anomalies

The iterative reduction of anomalies reflects the "nested" nature of the anomaly detection process.

Conclusions

The choice of four iterations was effective, allowing the model to refine anomaly detection. Further iterations are expected to converge as the kernel set increasingly represents normal nodes in nested anomalies.

01

02

The results align with those achieved by our supervisors, confirming the validity of our approach.

Histograms across thresholds (5%, 10%, 20%) were similar but had key differences:
At 20%, more nodes were flagged, making it assertive in detection but less precise.
At 5%, only extreme anomalies were captured, missing subtler ones.

03

The 10% threshold balanced precision and recall?

04

While the results are good, we could explore alternative methods like Kernel Sum to potentially improve anomaly detection.

Verification Plan

	Name	Description	Expected Output
Case 1	Insufficient Data	The graph contains too few nodes or edges to effectively train the model.	A warning message is displayed, suggesting providing more data.
Case 2	Incorrect Anomaly Threshold	The user sets an inappropriate threshold for classifying nodes as anomalies.	The model might misclassify nodes as normal or anomalous.
Case 3	Evaluation Metrics Mismatch	The chosen evaluation metrics (e.g., precision, recall, F1-score) are not aligned with the specific task or dataset.	The model's performance might be misinterpreted.
Case 4	Model Training Failure	The model fails to train due to issues like hyperparameter tuning, convergence problems, or insufficient computational resources.	An error message is displayed, indicating the failure and suggesting potential solutions.
